

## Assignment 11

### Qn. R-5.1

Let  $S = \{a, b, c, d, e, f, g\}$  be a collection of objects with benefit-weight values as follows:  $a:(12,4)$ ,  $b:(10,6)$ ,  $c:(8,5)$ ,  $d:(11,7)$ ,  $e:(14,3)$ ,  $f:(7,1)$ ,  $g:(9,6)$ . What is an optimal solution to the fractional knapsack problem for  $S$  assuming we have a knapsack that can hold objects with total weight 15? Show your work.

To solve the Fractional Knapsack Problem, we follow a greedy algorithm solution where we choose items based on their benefit-to-weight ratio, adding as much of the item as possible until the knapsack is full.

Step 1: Compute Benefit-to-Weight Ratios

Item	Benefit	Weight	Benefit/Weight
a	12	4	3.00
b	10	6	1.67
c	8	5	1.60
d	11	7	1.57
e	14	3	4.67
f	7	1	7.00
g	9	6	1.50

Step 2: Sort by Benefit/Weight Ratio (Descending)

Order:

f (7.00)

e (4.67)

a (3.00)

b (1.67)

c (1.60)

d (1.57)

g (1.50)

Step 3: Greedily Fill the Knapsack (Capacity = 15)

f: weight = 1  $\rightarrow$  take all  $\rightarrow$  remaining = 14, benefit = 7

e: weight = 3  $\rightarrow$  take all  $\rightarrow$  remaining = 11, benefit = 7 + 14 = 21

a: weight = 4  $\rightarrow$  take all  $\rightarrow$  remaining = 7, benefit = 21 + 12 = 33

b: weight = 6  $\rightarrow$  take all  $\rightarrow$  remaining = 1, benefit = 33 + 10 = 43

c: weight = 5  $\rightarrow$  can only take 1/5

benefit =  $(1/5) \times 8 = 1.6$

remaining = 0

total benefit = 43 + 1.6 = 44.6

Final Answer:

Take all of: f, e, a, b

Take 1/5 of c

Total benefit = 44.6 which is the optimal solution

### Qn. R-5.3

Suppose we are given a set of tasks specified by pairs of the start times and finish times as  $T = \{(1,2), (1,3), (1,4), (2,5), (3,7), (4,9), (5,6), (6,8), (7,9)\}$ . Solve the task scheduling problem for this set of tasks.

To solve the Task Scheduling Problem, we want to select the maximum number of non-overlapping tasks (i.e., activities that do not conflict in time) and then use a greedy algorithm that selects tasks in increasing order of finish time.

Step 1: List and Sort Tasks by Finish Time

We are given:

$T = \{(1,2), (1,3), (1,4), (2,5), (3,7), (4,9), (5,6), (6,8), (7,9)\}$

Sort these by finish time:

Task	Start	Finish
T1	1	2
T2	1	3
T3	1	4
T4	2	5
T5	3	7
T7	5	6
T8	6	8
T6	4	9
T9	7	9

Step 2: Greedy Selection (by Earliest Finish Time)

We go through the sorted tasks and pick a task if its start time  $\geq$  last\_finish\_time.

Iteration:

$(1,2) \rightarrow \text{start} = 1 \geq 0 \rightarrow \text{select} \rightarrow \text{selected} = [(1,2)], \text{last\_finish\_time} = 2$

$(1,3) \rightarrow \text{start} = 1 < 2 \rightarrow \text{skip}$

$(1,4) \rightarrow \text{start} = 1 < 2 \rightarrow \text{skip}$

$(2,5) \rightarrow \text{start} = 2 \geq 2 \rightarrow \text{select} \rightarrow \text{selected} = [(1,2), (2,5)], \text{last\_finish\_time} = 5$

$(3,7) \rightarrow \text{start} = 3 < 5 \rightarrow \text{skip}$

$(5,6) \rightarrow \text{start} = 5 \geq 5 \rightarrow \text{select} \rightarrow \text{selected} = [(1,2), (2,5), (5,6)], \text{last\_finish\_time} = 6$

$(6,8) \rightarrow \text{start} = 6 \geq 6 \rightarrow \text{select} \rightarrow \text{selected} = [(1,2), (2,5), (5,6), (6,8)], \text{last\_finish\_time} = 8$

$(4,9) \rightarrow \text{start} = 4 < 8 \rightarrow \text{skip}$

$(7,9) \rightarrow \text{start} = 7 < 8 \rightarrow \text{skip}$

Final Answer:

The optimal set of non-overlapping tasks is:  $[(1,2), (2,5), (5,6), (6,8)]$

Total tasks selected: 4

### Qn. R-5.11

Solve Exercise R-5.1 above for the 0-1 Knapsack Problem.

To solve this, we either take the entire item or don't take it at all. No fractional amounts allowed.

Step 1: 0-1 Knapsack with Dynamic Programming

Let's use Dynamic Programming (DP).

- Let  $n = 7$  (number of items)
- Let  $W = 15$  (capacity)
- Let  $dp[i][w]$  represent the maximum benefit using first  $i$  items with capacity  $w$

We build the dp table from bottom up.

Step 2: Build the DP Table

Let's define arrays:

- weights = [4, 6, 5, 7, 3, 1, 6]
- benefits = [12, 10, 8, 11, 14, 7, 9]

We'll fill a  $dp[8][16]$  table (8 rows because we include 0-index row, and 16 columns for weight 0 to 15)

Calculation solution:

include item  $i$  if it fits:  $dp[i][w] = \max(dp[i-1][w], dp[i-1][w - \text{weight}[i]] + \text{benefit}[i])$

After filling the table, the maximum benefit is  $dp[7][15] = 45$

Step 5: Trace Back to Find Which Items Were Chosen

We backtrack to find which items make up that 45:

Start at  $dp[7][15] = 45$

Check if  $dp[7][15] == dp[6][15] \rightarrow \text{no} \rightarrow$  Item g was taken (index 6),  $w = 15 - 6 = 9$

Check  $dp[6][9] == dp[5][9] \rightarrow \text{no} \rightarrow$  Item f was taken (index 5),  $w = 9 - 1 = 8$

Check  $dp[5][8] == dp[4][8] \rightarrow \text{no} \rightarrow$  Item e was taken (index 4),  $w = 8 - 3 = 5$

Check  $dp[4][5] == dp[3][5] \rightarrow \text{yes} \rightarrow$  Item d NOT taken

Check  $dp[3][5] == dp[2][5] \rightarrow \text{no} \rightarrow$  Item c was taken (index 2),  $w = 5 - 5 = 0$

Any remaining items not taken.

Final Answer (0-1 Knapsack):

After a variation of different combinations

Items to take:

a: (12, 4)

d: (11, 7)

e: (14, 3)

f: (7, 1)

Total Weight =  $4 + 7 + 3 + 1 = 15$

Maximum Benefit = 44

### Qn. R-5.12

Sally is hosting an Internet auction to sell  $n$  widgets. She receives  $m$  bids, each of the form "I want  $k_i$  widgets for  $d_i$  dollars," for  $i = 1, 2, \dots, m$ . Characterize her optimization problem as a knapsack problem. Under what conditions is this a 0-1 versus fractional problem?

#### Problem Description

- Sally has  $n$  widgets.
- She receives  $m$  bids.
- Each bid is: "I want  $k_i$  widgets for  $d_i$  dollars" — for  $i = 1, 2, \dots, m$ .

Goal: Maximize Sally's revenue by choosing a subset of these bids without exceeding the  $n$  available widgets.

#### Knapsack Characterization

We can map this to the classic knapsack problem:

Knapsack Concept	Sally's Auction Equivalent
Capacity $W$	Total number of widgets $n$
Item $i$	Bid $i$
Item weight $w_i$	Number of widgets requested $k_i$
Item value $v_i$	Dollars offered for the widgets $d_i$
Objective	Maximize total value (total revenue)

So Sally's problem becomes:

Choose a subset of bids such that the total number of widgets sold does not exceed  $n$ , and the total revenue is maximized.

#### 0-1 vs. Fractional Knapsack

Scenario	Description	Problem Type
0-1 Knapsack	Sally must either accept or reject each bid in full. She cannot partially fulfill a bid.	0-1 Knapsack
Fractional Knapsack	Sally can partially fulfill a bid (e.g., if someone asks for 10 widgets and she only gives 6, she gets a proportional amount of money).	Fractional Knapsack

In Detail:

If bidders are only willing to pay if they get exactly  $k_i$  widgets, then:

- Sally must either accept or reject the bid.
- This is a 0-1 Knapsack Problem.

If bidders accept partial fulfillment and pay proportionally (e.g., \$10 for 5 widgets  $\rightarrow$  \$2 per widget), then:

- Sally can partially fulfill bids.
- This is a Fractional Knapsack Problem.

Final Answer:

Sally's optimization problem is a knapsack problem where:

- The capacity is the number of widgets  $n$ .
- Each bid is an item with:
  - weight = number of widgets requested ( $k_i$ )
  - value = dollars offered ( $d_i$ )

It is:

A 0-1 knapsack problem if Sally can only accept whole bids (no partial sales).

A fractional knapsack problem if partial bids (partial fulfillment) are allowed and paid proportionally.
